

Health Equity from an Actuarial Perspective Managing Population Health

Rebecca Sheppard, MAAA, FSA, MHS, Co-Chairperson, Health Equity Committee
Cori Uccello, MAAA, FSA, FCA, MPP, Senior Health Fellow

Presentation to AHIP
December 12, 2023

About the Academy

- The American Academy of Actuaries is a 19,500-member professional association whose mission is to serve the public and the U.S. actuarial profession. For more than 50 years, the Academy has assisted public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues.
- The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.

For more information, please visit:

www.actuary.org

Why actuaries care about health equity

- Key health decision-makers rely on actuaries for advice
- Unique skillset to quantify costs of health disparities to the health care system
- Commitment to identifying and addressing issues on behalf of the public interest
- Desire to explore and understand whether any actuarial practices inadvertently lead to or exacerbate health disparities and inefficient use of health care dollars
- Potential to use actuarial principles to reduce health disparities and improve health outcomes

American Academy of Actuaries Health Equity Committee

- Created to contribute actuarial perspective to health equity
- Focus:
 - Evaluate actuarial practices in the context of health equity
 - Educate actuaries and other stakeholders on health equity issues
 - Apply an equity lens when considering the impact of current or proposed health care policies

Definitions used by the Health Equity Committee

Health Equity: Everyone has a fair and just opportunity to be as healthy as possible. This requires removing obstacles to health such as poverty, discrimination, and their consequences, including powerlessness and lack of access to good jobs with fair pay, quality education and housing, safe environments, and health care.

Health Disparities: Differences in health or its key determinants that adversely affect marginalized or excluded groups. Disparities in health and in the key determinants of health are the metric for assessing progress toward health equity.

Social Determinants of Health: Nonmedical factors such as employment, income, housing, transportation, child care, education, discrimination, and the quality of the places where people live, work, learn, and play, which influence health.

Initial phase—Discussion brief developed a list of questions and topics to explore further

- Comprehensive list served as starting point for further analysis
- Four areas of focus:
 - Health plan pricing
 - Health plan benefit design
 - Provider contracting and network development
 - Population health management

Subsequent papers explored issues in more detail

DISCUSSION BRIEF—ISSUE IN FOCUS | MAY 2021

Health Equity from an Actuarial Perspective Health Plan Pricing

The American Academy of Actuarial Health Practice Council created the Health Equity Work Group with a goal of contributing to efforts promoting health equity and ensuring health equity among racial and ethnic minority populations. The work group is committed to assess the extent to which they may offer appropriate, adequate actuarial and other solutions to the Academy's health equity work.

A discussion brief introduced the first phase in which health actuaries are involved that is a question and topics to explore further. This first phase content and findings are now questions, pricing health insurance products. Other brief length design provides contracting and terms.

Taken together, the series forms the foundation for the next phase of the group's work—investigation and analysis to answer the questions. By sharing an actuarial perspective through this series, the work group hopes to actively engage not only the actuarial profession, but also policymakers and the health equity community, to help advance the public discourse on health equity solutions.

The Health Equity Work Group has found 3 normative factors to use in the following definitions in its work:

Health equity means that everyone has a fair and just opportunity to be as healthy as possible. This requires removing obstacles to health such as poverty, discrimination, and risks; increasing opportunities and access to good jobs with fair pay, quality education and housing, safe environments, and health care.

Health disparities are differences in health or key determinants that adversely affect marginalized or excluded groups. Disparities in health and in the determinants of health are the metrics for assessing progress toward health equity.

Health equity means that everyone has a fair and just opportunity to be as healthy as possible. This requires removing obstacles to health such as poverty, discrimination, and risks; increasing opportunities and access to good jobs with fair pay, quality education and housing, safe environments, and health care.

DISCUSSION BRIEF—ISSUE IN FOCUS | JULY 2021

Health Equity from an Actuarial Perspective Health Plan Benefit Design

The American Academy of Actuarial Health Practice Council created the Health Equity Work Group with a goal of contributing to efforts to reduce health disparities and improve health equity among racial and ethnic minority populations and underserved or under-resourced communities. The work group is committed to assess the extent to which they may offer health equity and incremental change where appropriate, adequate actuarial and other solutions on health equity issues, and apply its equity lens to the Academy's health equity work.

An initial discussion brief, *Health Equity from an Actuarial Perspective: Questions to Explore*, introduced the first phase of the work group's work—an identification of areas in which health actuaries are involved that may affect health equity and development of a list of questions and topics to explore further. This discussion brief is part of a follow-up series providing more content and details on these questions. This discussion brief focuses on questions related to health benefit design. Another brief, *Health Plan Pricing and Contracting*, will be published in the near future.

Taken together, the series forms the foundation for the next phase of the group's work—investigation and analysis to answer the questions. By sharing an actuarial perspective through this series, the work group hopes to actively engage not only the actuarial profession, but also policymakers and the health equity community, to help advance the public discourse on health equity solutions.

AMERICAN ACADEMY OF ACTUARIES

Issue Brief

Health Risk Assessment and Risk Adjustment in the Context of Health Equity

AUGUST 2023

Key Points

- Risk assessment and risk adjustment—valuable tools that are used for a variety of purposes in health care and health insurance systems—are being re-examined to understand whether and how they should incorporate social risk factors.
- When risk-adjusting providers to health insurance plans, directly including social risk factors could exacerbate disparities, but other techniques are available to that may prevent or offset social risk.
- When measuring or providing provider performance, it may be appropriate to adjust the social factors when outcomes measures reflect both outside of provider control.
- Care must be taken to ensure that algorithms used to help target care management to high-risk patients are not based against patients with greater social risk.
- Additional publications by the Academy's Health Equity Committee are available on the Academy's website.

Risk assessment and risk adjustment—valuable tools that are used for a variety of purposes in health care and health insurance systems. They are used to adjust premium payments to health insurance plans so that plans are not over- or under-paid relative to the health of their enrollees. They are also used on programs that treat or prevent health care providers based on health care outcomes that are not entirely preventable or controllable by factors outside of their control. In both of these instances, the use of risk adjustment is critical to helping ensure access to health insurance coverage and health care services among people who are at higher risk of using health care services or who have more complex health care needs. These tools can also be used to help identify individuals who would benefit from care management programs.

The Health Equity Committee has found it imperative to take the following definitions in its work:

Health equity means that everyone has a fair and just opportunity to be as healthy as possible. This requires removing obstacles to health such as poverty, discrimination, and risks; increasing opportunities and access to good jobs with fair pay, quality education and housing, safe environments, and health care.

Health disparities are differences in health or in key determinants that adversely affect marginalized or excluded groups. Disparities in health and in the key determinants of health are the metrics for assessing progress toward health equity.

Social determinants of health are nonmedical factors such as employment, income, housing, transportation, child care, education, discrimination, and the quality of the places where people live, work, learn, and play that influence health.

Health equity and managing population health

In what ways can efforts to assess health risks and efforts to address these risks affect health disparities?

one-year time horizon
program assessment metrics
wellness programs
financial risk
care management
proxy data
complex algorithms
disease management
social determinants of health
specific populations
choice of data
return on investment

Population health definitions

- Population health: health outcomes of a defined group of individuals, including the distribution of such outcomes within the group
- Population health management: the processes used to improve health outcomes of a population

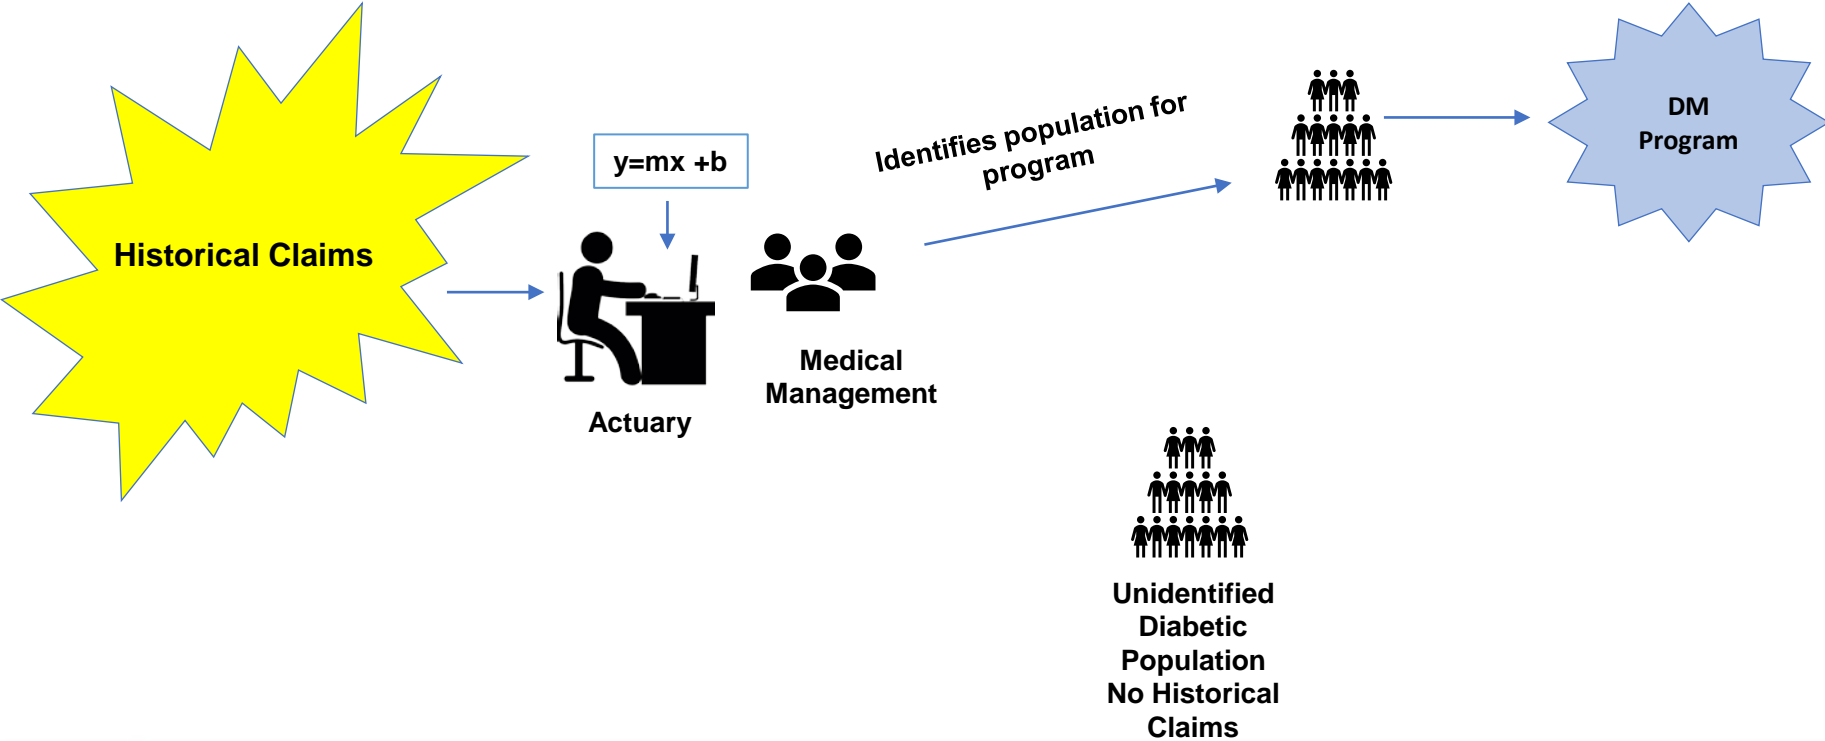

Actuarial considerations in managing population health

- Defining the population and determining outcome measures
- Interpreting large data sets
- Developing and managing complex algorithms
- Collaborating with cross-functional teams
- Measuring financial risk
- Conducting cost/benefit analyses

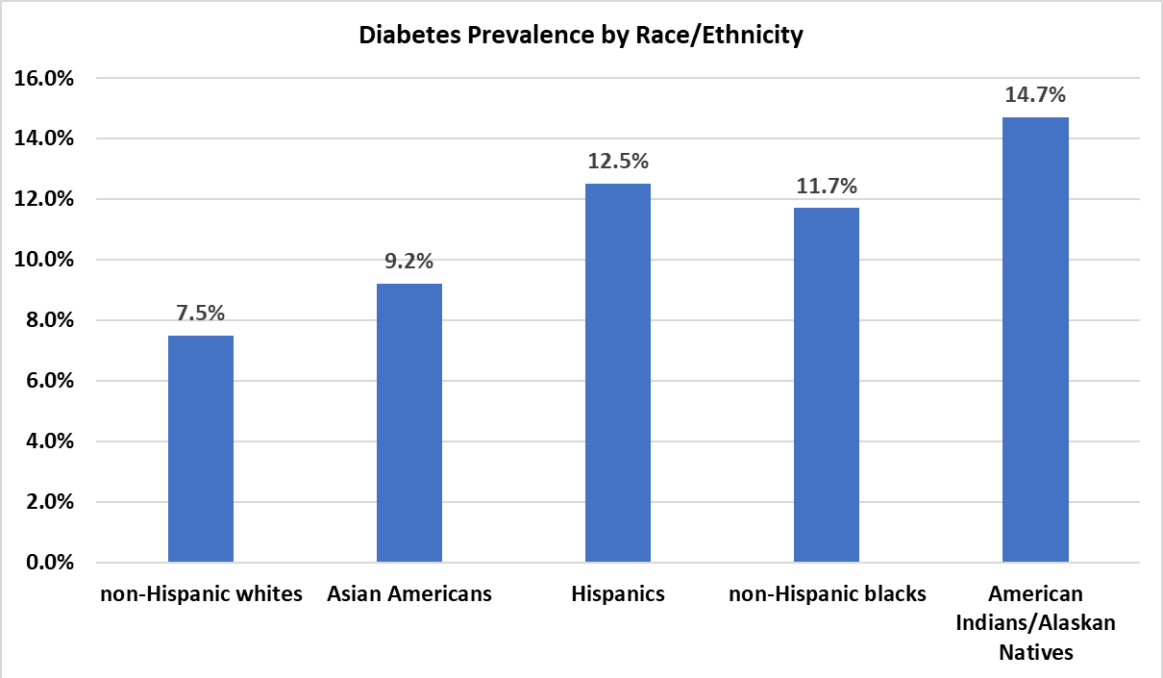

Algorithms and proxy data

- Used to identify individuals who are eligible for the intervention
 - Interventions may be wellness based or disease focused
- Claims data is generally used but does not necessarily reflect need
 - Can lead to bias by de-prioritizing individuals with lower claim cost even if they would benefit from the intervention
- Testing algorithms could identify racial, gender, or other types of bias (may require collecting demographic data)

Population Health Example: Diabetes Management Program

Population Health: Diabetes Management Program_(cont.)

Addressing Social Determinants of Health (SDOH)

- Predictive analytics and data mining can be used to identify individuals needing SDOH support
 - Can help overcome some limitations of claims data
- Interventions to improve health outcomes may not be directly related to healthcare, e.g.,:
 - Renovating public housing to address asthma
 - Building supermarket in a “food desert”
 - Investing in transportation services
- SDOH interventions may not be as easily implemented in the context of a health plan
- Legal/regulatory hurdles may impede the design of care management programs
- “One size fits all” may not work when designing solutions to address SDOH needs

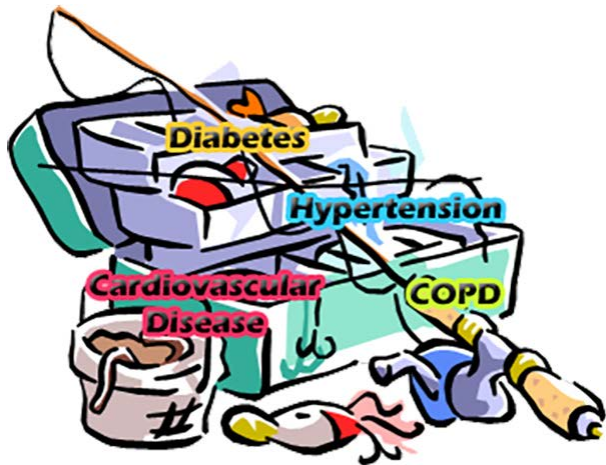

Time horizon

- Cost/benefits of interventions are often measured over a one-year time horizon
 - Most insurance plans reset on an annual basis and members/employees may turnover
- This short time horizon could undervalue benefits that take longer to materialize
 - For populations with lower utilization, this may exacerbate real or perceived disparities

Measuring outcomes

- Return on Investment (ROI) is often used to make decisions about programs but it may focus too heavily on financial results
- Looking at average results over an entire population may not show the benefit for specific marginalized populations
- Including quality metrics, in addition to financial outcomes, may be a way to highlight and ultimately reduce health disparities

Using Risk Assessment to Target Disease Management and Care Management Programs

Goal:
To identify patients who would most benefit from these programs

Identifying Patients for Disease and Care Management Programs

- Eligible plan members can be identified through:
 - claims-based algorithms
 - risk stratification based on risk assessments of underlying conditions and whether outcomes can be improved through interventions
- If predicting costs is part of the identification process, could deprioritize members with lower costs, even if they have higher needs
 - Lower costs may indicate lower access to care rather than lower health care needs

Example of Algorithmic Bias

RESEARCH ARTICLE

ECONOMICS

Dissecting racial bias in an algorithm used to manage the health of populations

Ziad Obermeyer^{1,2*}, Brian Powers³, Christine Vogel⁴, Sendhil Mullainathan^{5*†}

Health systems rely on commercial prediction algorithms to identify and help patients with complex health needs. We show that a widely used algorithm, typical of this industry-wide approach and affecting millions of patients, exhibits significant racial bias: At a given risk score, Black patients are considerably sicker than White patients, as evidenced by signs of uncontrolled illnesses. Remedying this disparity would increase the percentage of Black patients receiving additional help from 17.7 to 46.5%. The bias arises because the algorithm predicts health care costs rather than illness, but unequal access to care means that we spend less money caring for Black patients than for White patients. Thus, despite health care cost appearing to be an effective proxy for health by some measures of predictive accuracy, large racial biases arise. We suggest that the choice of convenient, seemingly effective proxies for ground truth can be an important source of algorithmic bias in many contexts.

<https://www.science.org/doi/10.1126/science.aax2342>

- Algorithm used to identify patients with complex care needs
- At a given risk score, Black patients are sicker than white patients
- Bias arises because algorithm predicts health costs rather than illness
- Authors estimate that eliminating the bias could nearly double the Black patients selected

Options to Address Bias

- Rather than using health care costs, base algorithms on other predictors of need (e.g., avoidable costs, chronic conditions)
- Adjust spending data to better reflect health care needs
- Use constrained regressions
- Incorporate social risk factors when appropriate

Additional Resources

- Algorithmic Bias Playbook (Obermeyer, et al.)

<https://www.chicagobooth.edu/research/centefor-applied-artificial-intelligence/research/algorithmiebias>

Area-Level Social Risk Measures

Goal:

- Help measure and understand how the social determinants of health at the community level affect health-related social needs at the individual level

Potential Uses of AreaLevel Risk Measures

- Target funding for healthrelated social needs
- Adjust payments to health insurance plans
- Adjust payments to providers
- Incorporate into risk assessments

Selected Area-Level Indices

- **Area Deprivation Index**
- **Social Vulnerability Index**
- **Social Deprivation Index**
- AHRQ Socioeconomic Status Index
- Baseline Resilience Indicators for Communities
- California Healthy Places Index
- Census Bureau Community Resilience Estimates
- Child Opportunity Index 2.0
- Community Need Index
- Community Resilience Indicator Analysis
- COVID-19 Vaccine Coverage Index
- COVID-19 Community Vulnerability Index
- Distressed Communities Index
- Healthiest Communities
- Material Community Deprivation Index
- Modified Darden-Kamel Composite Socioeconomic Index
- Multidimensional Deprivation Index
- Multidimensional SDOH Index
- National Risk Index
- Neighborhood Concentrated Disadvantage Index
- Neighborhood Deprivation Index
- Neighborhood Socioeconomic Status
- Neighborhood Stress Score
- Opportunity Index
- Social Capital Index
- Social Vulnerability to Environmental Hazards Index
- Townsend Deprivation Index
- U.S. Prosperity Index

Indices Vary in Many Important Ways

- Domains included (e.g., socioeconomic position, race, gender, residential context, social needs)
 - Specific indicators within domains
 - How indicators are weighted
 - Unit of analysis (e.g., census block group, census tract, ZIP code, county)
 - Data source, update frequency, and most recent year available
 - Availability; cost to access
- When contemplating the use of an index, it's important to understand how the index was developed and its appropriateness to the specific project and goal

Some Key Issues With Using Area Level Measures

- The population represented in the index often differs from the population being risk adjusted.
- For many indices, the geographic unit of analysis is large enough that many cells won't be homogeneous.
 - Variance of characteristics within a cell will affect appropriateness of applying the index at an individual level
