AMERICAN ACADEMY of ACTUARIES

# Report on Principles-Based Reserves for Universal Life with a Secondary Guarantee based on a Shadow Fund from the American Academy of Actuaries’ Life Reserves Work Group <br> Presented to the National Association of Insurance Commissioners' Life and Health Actuarial Task Force 

April 2006

The American Academy of Actuaries is a national organization formed in 1965 to bring together, in a single entity, actuaries of all specializations within the United States. A major purpose of the Academy is to act as a public information organization for the profession. Academy committees, task forces and work groups regularly prepare testimony and provide information to Congress and senior federal policy-makers, comment on proposed federal and state regulations, and work closely with the National Association of Insurance Commissioners and state officials on issues related to insurance, pensions and other forms of risk financing. The Academy establishes qualification standards for the actuarial profession in the United States and supports two independent boards. The Actuarial Standards Board promulgates standards of practice for the profession, and the Actuarial Board for Counseling and Discipline helps to ensure high standards of professional conduct are met. The Academy also supports the Joint Committee for the Code of Professional Conduct, which develops standards of conduct for the U.S. actuarial profession.

This report illustrates principles-based reserves for Universal Life policies with secondary guarantees, and compares the results to current reserves under AG 38.

The policies used for illustration are shadow fund designs, and the assumed premium pattern is level annual premiums. Two issue ages are studied, age 45 and age 75 , both for select male insureds. The policies are priced to be profitable under the best-estimate experience assumptions used in this example. Details of the product design, pricing, and experience assumptions are attached in Exhibits 1 and 3. Pricing assumptions are strictly for illustrative purposes and should be presumed to be appropriate for pricing only in the context of these illustrations. Mortality assumptions reflect select experience that is better than 2001 CSO.

The reserves illustrated in this report are based on assumptions beyond the product design and pricing assumptions. The company is assumed to hold an investment portfolio with a book yield of $6.0 \%$ net of defaults and investment expenses. Investments in the portfolio are assumed to mature over the 10 years following the valuation date. In addition, the interest rates on the valuation date are assumed to be those of September 2004, when market interest rates were relatively low. As a result, the discount rate used for deterministic reserves tends to start near $6 \%$ and declines by projection year due to assumed re-investment at lower interest rates. All future investments are assumed to be in 10-year bonds, with a net spread of 70 basis points over Treasuries, net of defaults and expenses. The interest rate generator used for stochastic scenarios is the one currently in use for C-3 Phase I RBC.

Exhibit 4 illustrates deterministic reserves at various levels of margins in the assumptions. Levels 1 to 3 are similar to those used in our earlier report on 20-year term. Level 4 margins lead to breakeven at issue. That is, they approximately equate the present value of premiums with the present value of benefits and expenses in the deterministic scenario. Level 5 margins represent the minimum that might be allowed, and are discussed later in the "Note on pricing" section. Note that Exhibit 4 shows only the deterministic reserve, not the stochastic reserve.

Exhibit 5 illustrates the deterministic and stochastic reserves for a simulated inforce block consisting of business issued over the last 20 years. The results indicate that the stochastic reserve at the 65CTE level exceeds the deterministic reserve by about $6 \%$. This is an indication of the importance of including the stochastic calculation when reserving for products such as this with significant tail risk.

The results in Exhibit 5 also show that the stochastic reserve at the 65CTE level is $18 \%$ less than the current AG38 reserve for this simulated block of business. While it is dangerous to generalize, this suggests that reserves under AG38 are higher than principles-based reserves for this product with the assumed experience.

Exhibit 6 shows how the emergence of earnings might be affected by a change to principlesbased reserves and RBC for this product. The operating statement at the top of the page uses principles-based reserves with level 4 margins, while the operating statement at the bottom of the page uses AG38 reserves. Both statements show a substantial first year loss due to heavy acquisition costs. However, most of that loss is recovered in the second year when using principles-based reserves, while significant losses occur in several later years when using AG38 reserves.

The remainder of this report consists of other observations arising from our analysis of the sample UL policies with secondary guarantees.

## Competitive nature of the market

The premiums for issue age 45 and 75 were set at a level that would produce a profit in the range of that historically reported by life insurers under the experience assumptions used in this example. The market perspective in Exhibit 2 indicates that the age 45 premium is competitive, but the age 75 premium is not as competitive.

Several observers have noted that the current market at older issue ages is highly competitive. Insurers may be able to earn a profit at lower premium levels if their experience is different than that assumed for purposes of these illustrations. Such experience could include lower expenses, better mortality, higher lapse rates or higher investment returns.

In competitive markets like this, profit margins in pricing can be squeezed. Under the principlesbased approach, if premiums are set unusually low, all else being equal, the reserve would be higher. That's because the present value of premiums is an offset to the present value of benefits. If premiums are lowered while the present value of benefits is unchanged, then the reserve will be higher.

## Mortality improvement

The best estimate assumptions used in pricing include future mortality improvement. For these illustrations we used a mortality projection scale with rates of improvement that varied by attained age. The rates of improvement used were $1.00 \%$ per year for attained ages $0-60$, declining by $0.04 \%$ per year for each age over 60 , to zero at attained age 85 . The improvement was applied exponentially, as in (1-r) ${ }^{\mathrm{n}}$ rather than arithmetically, as in (1-nr).

While mortality improvement assumptions were used in pricing, they did not have a significant impact on the premiums set for either cell. This may have resulted from grading off the improvement assumed at older ages, where most death claims occur.

The draft model regulation does not allow a provision for mortality improvement in the reserve assumptions. Nevertheless, we recognize that under current conditions with a long historical trend of improvement, the assumption of no future mortality improvement represents part of the margin for conservatism in the reserve.

## Note on pricing

We reflected principles-based reserves and RBC in our pricing of the illustrated products. Since one pricing measure was the IRR on distributable earnings, we needed reserves and RBC by policy duration. Since the stochastic reserve is calculated in the aggregate and not by duration, we needed an approximate way to attribute a portion of the stochastic add-on to the deterministic reserve for the inforce to individual policies at each duration. After some research ${ }^{1}$ we developed the following approximations for this purpose:

[^0]> Excess of stochastic reserve over deterministic reserve $=$ $18 \%$ of premium $+2.7 \%$ of deterministic reserve

> Excess of capital requirement (for C3 only) over stochastic reserve = $25 \%$ of premium $+3.0 \%$ of deterministic reserve

Note that the add-on for the stochastic reserve should be considered when determining the level of reserve margins that lead to "breakeven" at issue. The deterministic reserve at issue must be negative if the stochastic reserve is to be zero. With this in mind, Exhibit 4 shows deterministic reserves with margins at level 5 , which is "minimum" margins consisting of the deterministic interest rate scenario and no mortality improvement. The deterministic reserve at issue is negative, but with the stochastic add-on the reported reserve would be positive, indicating a loss at issue.

For illustrative purposes, we used 90CTE in our pre-tax calculation as RBC for the C3 risk. The results of the stochastic valuation show that the 90CTE exceeds the 65CTE by $6 \%$.

## Z-values

A value called " $Z$ " has been proposed as a measure of the size of risk margins included in a reserve. $Z$ is calculated as:
$\mathrm{Z}=($ (reserve held) - (best estimate liability) ) / (present value of projected capital requirements)
where,
the best estimate liability is the deterministic reserve calculated using best estimate assumptions with no cash value floor; and
the present value of the projected capital requirements is the value of an annuity whose annual payment is the amount of capital held in that year to back the liability, using the same discount rates as are used for the deterministic reserve.

Theoretically, Z is the excess of the pre-tax return on equity over the investment yield. However, this theory doesn't explain why the Z values shown for this product are so high. The pricing pre-tax IRR is $12 \%$ or $13 \%$ (depending on issue age) and the investment return is $6 \%$, so why is Z greater than $7 \%$ when measured at time of issue?

The answer lies in the fact that in this situation, the denominator of Z understates the total capital requirement. The denominator includes only the explicit amount of capital held in excess of reported reserves. However, the reserves used in calculating the pricing IRR were at a level that creates a loss at issue. The loss at issue means that the reserves include an implicit extra capital requirement that is not included in the denominator when calculating Z . Because the denominator understates the full capital requirement, Z is higher than the pricing IRR would imply. Nevertheless, this higher value of Z does accurately reflect the degree of margin included in the reserve.

For this study we calculated the pricing IRR using stochastic reserves with minimum margins (level 5). Minimum margins consist of the deterministic scenario for discount rates and no mortality improvement. While the deterministic reserve shown in Exhibit 4 is negative at issue when using level 5 margins, the stochastic reserve would be positive. As was noted earlier in this report, the stochastic reserve would exceed the deterministic reserve at issue by about $18 \%$ of premium.

## Effect of investment strategy

Some observers have suggested that the investment strategy of using 10-year bonds is not appropriate for this product with its long-term guarantees. Therefore we studied the effect of changing the company's investment strategy from investing in 10 -year bonds to investing in 20-year bonds. With that change to both the existing portfolio on the valuation date and the strategy for future new investments, we expected the following effects:

1. The reserve for the inforce block may be reduced because the discount rate would be higher. The discount rates would be higher because the portfolio earned rate would be higher. The existing assets would run off more slowly and less money would be re-invested at current low interest rates. The 20-year strategy also means that future investments would generally be made at higher returns (than under the 10-year strategy) due to the typically positive slope of the yield curve.
2. The tail risk might be reduced due to better matching of assets and liabilities.

Exhibit 7 shows the reserves based on this change in assumed investment strategy. Both the deterministic and stochastic reserves are reduced by about $6 \%$ compared to using the 10 -year investment strategy under these conditions. However, the stochastic reserve is still substantially higher than the deterministic reserve. Since much of the interest rate risk with this product is related to interest rates at which future premiums will be invested, it appears that lengthening the term of assets that are purchased narrows the distribution of the stochastic reserve only slightly, although the entire distribution is shifted to a lower level.

* Required Surplus was calculated as 6\% of reserve plus $\$ 1.30$ per 1000 of Net Amount at Risk plus 25\% of premium.

## Exhibit 1 (continued)

## Shadow Fund Description

The shadow fund value at any duration equals the prior shadow fund value plus a net premium less a fund charge accumulated at an interest rate. All items are guaranteed.

- The net premium is $65 \%$ of the premium paid in a given year up to the target premium plus $50 \%$ in excess of the target premium.
- The fund charge is a defined "COI" times the face amount. Further, to the extent that the total fund charge in any policy year exceeds $65 \%$ of the target premium, only $10 / 13^{\text {th }}$ of the total fund charge in excess of the target premium is charged. For example, at issue age 45, the COI charge is 12.157988 per thousand, while the target premium is 8.40 per thousand. The COI charge against the fund is thus $\$ 8.40$ plus $10 / 13$ of $\$ 3.757988$, or $\$ 11.29076$ per thousand.
- The interest rate is prescribed and varies by duration 1-10, 11-20, and 21+. It also varies by issue age.

Details of shadow fund loads, COI charges, and interest rates are shown in the tables below.

| Male 45 Best Class Non-Tobacco |  |  |  |  |

| Per Unit | 1.29 | 73.74 |
|  |  | 10 |
| Commissions | $\underline{Y r s}$ | 1 |

* Mortality improvement is assumed on an attained age basis. The assumed rate of mortality improvement is $1.0 \%$ per year through attained age 60 , then declining by $0.04 \%$ per attained age to zero at attained age 85 . Since the improvement is by attained age, not by policy duration, no improvement in current mortality rates is assumed for attained ages over 85.

## Exhibit 4

The tables in Exhibit 4 require some explanation. There are two pages of tables. The first page shows values for issue age 45, and the second page shows values for issue age 75.

The top table on each page shows deterministic reserves by duration at several levels of margin. The columns on the left-hand side of the table shows parameters of the policy being valued, including the fund value and cash value. The right hand side of the table shows the deterministic reserves, with each column corresponding to a different level of margins. The far right hand column shows the deterministic reserve with no margins, that is, using best estimates.

The second table on each page shows the dollar amount of reserve margins. The numbers in each column reflect the excess of the reserve in that column of the first table over the best estimate liability in the right hand column of the first table.

The right-hand column in the second table shows the present value of required capital. This is the denominator for the Z values shown at the bottom of the table.

It is important to recognize that all of the figures shown in Exhibit 4 are deterministic reserves. The excess of the stochastic reserve over the deterministic reserve is not included.

| Total |  |

## Exhibit 7, part 2

These are the discount rates used in calculation of the seriatim, deterministic reserve in connection with the 20year investment strategy. Note that the "with margin" interest rates decline more slowly by projection year than those in Exhibit 3, part 2 because the portfolio rolls over more slowly so that the portfolio yield is less affected by the current low level of new money interest rates.

| Deterministic Interest Rates |  |  |
| :---: | :---: | :---: |
| Projection year |  |  |
|  |  | Margin |
| 1 | 6.00\% | 5.81\% |
| 2 | 6.00\% | 5.75\% |
| 3 | 6.00\% | 5.70\% |
| 4 | 6.00\% | 5.65\% |
| 5 | 6.00\% | 5.61\% |
| 6 | 6.00\% | 5.57\% |
| 7 | 6.00\% | 5.54\% |
| 8 | 6.00\% | 5.51\% |
| 9 | 6.00\% | 5.48\% |
| 10 | 6.00\% | 5.45\% |
| 11 | 6.00\% | 5.43\% |
| 12 | 6.00\% | 5.40\% |
| 13 | 6.00\% | 5.38\% |
