## Report from the joint American Academy of Actuaries/Society of Actuaries Payout Annuity Table Team, a joint subgroup of the Life Experience Subcommittee

2012 Individual Annuity Reserving Table
Presented to the National Association of Insurance Commissioners' Life Actuarial Task Force

September 2011

The American Academy of Actuaries is a 17,000-member professional association whose mission is to serve the public and the U.S. actuarial profession. The Academy assists public policymakers on all levels by providing leadership, objective expertise, and actuarial advice on risk and financial security issues. The Academy also sets qualification, practice, and professionalism standards for actuaries in the United States.

## I - Background and Scope

The objective of the Payout Annuity Table Team (Team), as requested by the NAIC's Life Actuarial Task Force (LATF), was to produce a new annuity valuation mortality table, including projection scales and margins necessary to make the table suitable for standard valuation purposes for individual annuities. This report documents the data, assumptions and process the Team used to develop the 2012 Individual Annuity Reserve Table (2012 IAR Table). The Team began with data and information from the mortality experience analysis, as described in the Society of Actuaries 2000-2004 Individual Payout Annuity Experience Report, dated April 2009. From this, the Team developed a basic table (2012 IAM Table), projection scale (Scale G2). Lastly, the Team explored various approaches and levels of margin which were discussed and ultimately recommended by LATF. The IAR Table is comprised of these three components, which are discussed throughout this report. In addition, the Team recommended and LATF concluded it made sense to develop a generational mortality table through the use of projection factors. While this represents a departure from previous individual annuitant mortality tables, it overcomes the disadvantage of using a static table that can become dated more quickly than a generational table.

## II - Table Development and Approach

The 2000-2004 Payout Annuity Mortality Experience Study includes experience for immediate annuities, annuitizations and life settlement options of individual life insurance and annuity death claims. The experience analyzed excluded substandard annuities, structured settlement annuities and variable payout annuities. The experience represented 16 companies over the exposure period. The aggregated annuitant data (male, female) provided for the periods 2000-2004 included death, exposure (initial exposed to risk) and amount of annual income for ages 50 to 113. The data presented some evidence of selection in the form of lower Actual-to-Expected ratios for nonrefund (i.e., life only with no certain period) immediate annuities at higher annual income levels. However, the Team decided that due to the limited data at these higher income levels and the narrow scope of this finding (unique to immediate annuities), it would avoid unnecessary complexity and not seek to differentiate mortality by annual income level.

For the purpose of developing the 2002 experience table, the age range was subsequently limited to ages 50 to 99 due to lack of credible experience at younger and older ages. To account for differences in data (extract) periods by the contributing companies, the death, exposure and amount of annual income data were summed across the 2000-2004 period. This data was then smoothed using a graduation approach which is described in detail in this report. Mortality rates were then developed for ages younger than 50 and older than 95 , and further adjustments were made to grade the rates for ages 50 to 65 up to the experience-based rates at age 65 . The methods used to develop or extrapolate the mortality rates for ages under 50 and above 95 , as well as other refinements and adjustments, are described within this report. See Section IV, Younger and Older Age Adjustments. The result of these efforts was a 2002 experience table.

The next step was to project this table with improvement factors to 2012 to create the 2012 Individual Annuity Mortality Basic Table (2012 IAM Basic Table). Once the decision was reached on the merits of creating a generational mortality table, the Team then proceeded with the development of an improvement scale to be used for years 2013 and beyond. Following the development of this scale, labelled projection Scale G2, a methodology to reflect mortality improvement between 2002 and 2012 was determined. Margin levels were then established and added to the 2012 IAM Basic Table to derive the 2012 IAM Period Table. The 2012 IAR Table consists of this 2012 IAM Period Table along with the use of Scale G2 to project future mortality improvements beyond 2012.

## III - Graduation

The Team analyzed various graduation approaches to create a preliminary table and ultimately decided to create a preliminary table using confidence intervals by applying the P-Spline methodology. The Team chose the P-Spline method as it was a practical statistical package designed and used by actuaries for mortality data, the output of the package is a statistically robust fitted life ("best estimate") table and the output provides a measure of uncertainty of the fitted table in the form of confidence intervals.

The P-Spline method was used to fit the dataset and provide a graduated life table with the mortality rates $\left(q_{x}\right)$ weighted by amount of annual income. Initially described by Eilers and Marx ${ }^{1}$, P-Splines comprise a subset of a class
of (piecewise) polynomial functions. They combine the use of P-Splines and difference penalties (e.g., on the estimated coefficients of a generalized linear regression model) to smooth and provide projections of the data.

The P-Spline application used was made available through a spreadsheet-based modeling tool (CMI Mortality Projection Spreadsheet version 3.0) provided by the Continuous Mortality Investigation Bureau or CMIB (http://www.actuaries.org.uk/research-and-resources/pages/continuous-mortality-investigation). ${ }^{2}$ Using the tool, values for $\mathrm{q}_{\mathrm{x}}$ (males or females) weighted by amount of annual income were fitted for each age x of the dataset. ${ }^{3}$ The surface fit was determined by a combination of the data and the penalty applied. Data smoothing was provided by means of the penalized splines and the $\log$ mean values of $q_{x}$ within the fitted region generated. ${ }^{4}$ Ninety-five percent confidence intervals ( $95 \%$ CI) were also calculated for $\mathrm{q}_{\mathrm{x}}$ based upon the standard deviations (adjusted for increased uncertainty due to analysis by amount of annual income) of the $\log$ mean values of $q_{x}$ generated by the tool.

This graduation approach resulted in mortality rates generally ranging between $99 \%$ and $101 \%$ of the best estimate mortality rates for key ages. However, the confidence intervals at the oldest and younger ages were wider, suggesting greater uncertainty. In addition, the resulting mortality rates at the older ages were higher than the Annuity 2000 Basic Table. The P-Spline application breaks down as data becomes limited and less credible, which was the case with the underlying younger and older age experience. Therefore, the Team explored additional methods to derive the mortally rates for the younger and older ages, as discussed in Section IV - Younger and Older Age Adjustments.

A comparison of the actual and smoothed mortality $\left(q_{\mathrm{x}}\right)$ values for males and females is provided in Figures 1 and 2, respectively.

Figure 1. Graduated Male Mortality Adjusted by Amount of Annual Income

Figure 2. Graduated Female Mortality Adjusted by Amount of Annual Income

## IV - Younger and Older Age Adjustments

The mortality experience at both the younger and older ages was limited. In analyzing the experience, the Team identified that the mortality rates at these ages had little impact on the final reserve. Therefore, the Team compared the results at specific ages to several existing industry tables, including: the 1994 Group Annuity Mortality Basic Table (GAM) projected with Scale AA to 2002 (the mid-point of the payout annuity experience period), the 2008 Valuation Basic RR100 Table (2008 VBT), the Annuity 2000 Basic Table (a2000 Table) and the 2006 U.S. Life Tables. Both the 1994 GAM and the a2000 Table had a reasonable fit for ages 20 and 35; however, the tables exhibited significant divergence from the underlying experience by age 50. In addition, the 1994 GAM was lower than the population mortality (2006 U.S. Life Tables) and the a2000 rates were significantly lower than both the population mortality rates and the more recent life experience table at the highest ages for the male risks.

## IV.A - Younger Ages

The Team researched the development of the a2000 Table and predecessor tables and found that the a2000 Table rates, at the younger ages, could reasonably be described as being based on group annuity active life experience from 1939-1947, projected with various mortality improvement scales for almost 60 years.

For attained ages 50-59, the 2000-2004 experience shows ratios to the a2000 Table of 191\% for males ( 245 deaths), and $231 \%$ for females ( 201 deaths). The Team considered that these high ratios might be caused by early retirements due to poor health. Past committees were not concerned about the actual experience for ages $50-59$ being significantly higher than the valuation table. The Team attributed this lack of concern to the fact that there was not much payout annuity business at these ages, and the lack of material impact of mortality rates at these ages on the reserves. The lack of material impact at younger ages stems from the fact that annuity reserves are a function of probability of survival, which is near 1 at younger ages. For instance, using the a2000 table, using two times a mortality rate at age $20(1.10$ per 1,000 instead of 0.55 per 1,000$)$ means the probability of survival (or receiving the next payment) would only decrease from 0.99945 to 0.99890 , or a $0.055 \%$ reduction in actuarial value. In addition, there probably was a desire that the annuity valuation mortality appear consistent with other tables, e.g., life insurance and population life tables. Based on the report for the 1983 IAM Table, the a1983 Committee seemed to desire having the annuity mortality rates generally be lower than ultimate life insurance table mortality.

Table 1 below compares the mortality rates for ages 20,35 and 50 , for the following tables:

1. a2000 Table
2. 1994 GAM Basic projected to 2002 using Projection Scale AA
3. 2008 VBT, Nonsmoker, Ultimate
4. 2006 Social Security Administration (SSA) Experience

Table 1 - Comparison of Mortality Rates (1000qx) at Low Attained Ages

| Table | Age 20 |  | Age 35 |  | Age 50 |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Male | Female | Male | Female | Male | Female |
| a2000 Table | 0.55 | 0.28 | 0.79 | 0.52 | 3.33 | 1.71 |
| 1994 GAM Basic projected to 2002 | 0.47 | 0.27 | 0.88 | 0.47 | 2.40 | 1.34 |
| 2008 VBT, NS | 0.88 | 0.31 | 1.02 | 0.50 | 2.48 | 1.77 |
| 2006 SSA | 1.34 | 0.46 | 1.67 | 0.90 | 5.66 | 3.28 |

The 1994 GAM Table projected to year 2002 is reasonably close to the a2000 table for ages 20 and 35 , and moderately lower at age 50 .

The 1994 GAM rates were developed as follows:

- Ages 1-12 are from the 1990 Life Tables published in SSA 107.
- Ages 13-24 are graded up to the age 25 experience rate for the Civil Service Retirement System (CSRS) active life experience.
- Ages 25-50 are the CSRS active life experience.
- Ages 51-65 are weighted averages between CSRS active and retired life experience, with the weights for active lives grading down from age 51 to 65 .
- Ages $66+$ used group annuity actual experience. There was not a large disconnect between age 65 and 66 , and later graduation smoothed the resulting table.
- All the experience rates were projected to 1994 prior to graduation.

After reviewing the various tables, the Team decided to use the 1994 GAM table, projected to 2002 using projection Scale AA for ages 1 through 45, and graded to the graduated (experience-based) rates at age 65. The grading was done such that the mortality rates have a constant percentage increase from age 50 to age 65 . Age 0 was set equal to four times the age 1 rate, which was consistent with the approach taken for developing the age 0 mortality for the 2008 VBT.

Tables 2 and 3 below illustrate the development of the 2012 IAM Basic Table rates at younger ages for quinquennial ages for male and female risks, respectively.

Table 2 - Development of Mortality Rates for 2012 IAM Basic Table Male Risks - Select Younger Ages

| Male <br> Age | $\mathbf{1 9 9 4}$ <br> GAM <br> Basic | Projection <br> Scale AA | $\mathbf{1 9 9 4}$ <br> GAM <br> Projected <br> to 2002 | Graduated <br> Data | Graded <br> Mortality |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{1 0 0 0} \mathbf{Q x}_{\mathbf{x}}$ | $2.00 \%$ | 0.217 |  |  |
| 5 | 0.255 | $2.00 \%$ | 0.180 |  | 0.217 |
| 10 | 0.212 | 2.00 |  | 0.180 |  |
| 15 | 0.371 | $1.90 \%$ | 0.318 |  | 0.318 |
| 20 | 0.545 | $1.90 \%$ | 0.467 |  | 0.467 |
| 25 | 0.711 | $1.00 \%$ | 0.656 |  | 0.656 |
| 30 | 0.862 | $0.50 \%$ | 0.828 |  | 0.828 |
| 35 | 0.915 | $0.50 \%$ | 0.879 |  | 0.879 |
| 40 | 1.153 | $0.80 \%$ | 1.081 |  | 1.081 |

| 55 | 2.466 | $0.80 \%$ | 2.313 | 4.808 | 2.743 |
| 60 | 4.773 | $0.50 \%$ | 4.585 | 6.007 | 4.738 |
| 65 | 9.286 | $0.50 \%$ | 8.921 | 8.185 | 8.185 |

## IV.B - Older Ages

Similar to the analysis for the younger ages, the Team researched the development of the a2000 Table and predecessor tables at the higher ages.

The a2000 Table mortality rates for the higher attained ages were developed as follows:

- As with the rates for the younger ages, the a2000 Table rates are the rates from the 1983 IAM Table projected 17 years using projection Scale G ( $100 \%$ for males and $50 \%$ for females). A cubic curve was fitted at the high ages, and rates were graded to 1.0 at age 115 .
- The a 1983 Table was based on the 1973 Experience Table, which was developed from the Society of Actuaries' 1971-76 experience study. At the older ages, the experience table was graduated with a formula that included a
cubic equation to grade to 1.0 by age 115 . These rates were then projected 9.5 years to 1983 , using $1.5 \%$ annual improvement. These rates were then re-graduated.

The level of improvement assumed in projecting the 1973 Experience Table to the a2000 Table was much higher than the observed mortality improvement in the US population over similar time periods. Table 4 below compares the assumed improvement used in the a1983 and a2000 Tables for select higher ages to the actual population improvement for similar periods of time.

Table 4 - Comparison of Annualized Improvement Rates in U.S Population, the a1983 and a2000 Tables for Select Higher Ages

|  | Male Age |  |  |  |  | Female Age |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Basis/Time Period | $\mathbf{8 2}$ | $\mathbf{8 7}$ | $\mathbf{9 2}$ | $\mathbf{9 7}$ | $\mathbf{8 2}$ | $\mathbf{8 7}$ | $\mathbf{9 2}$ | $\mathbf{9 7}$ |  |
| U.S. Life 1970-80 | $1.1 \%$ | $1.0 \%$ | $0.9 \%$ | $0.5 \%$ | $2.0 \%$ | $1.8 \%$ | $1.4 \%$ | $0.9 \%$ |  |
| U.S. Life 1980-00 | $1.0 \%$ | $0.7 \%$ | $0.4 \%$ | $0.2 \%$ | $0.5 \%$ | $0.4 \%$ | $0.3 \%$ | $0.2 \%$ |  |
| 1973-1983 for a1983 | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ | $1.5 \%$ |  |
| 1983-2000 for a2000 | $1.3 \%$ | $1.3 \%$ | $1.0 \%$ | $1.0 \%$ | $0.8 \%$ | $0.8 \%$ | $0.6 \%$ | $0.6 \%$ |  |

The Team noted that the actual to expected (A/E) ratios in the 2000-2004 experience study, where the expected basis was the a2000 Table, were relatively high. To understand why this might be, the Team analyzed the population improvement over the same time period versus that assumed in the a2000 Table. At the highest ages, the population improvement appears to have been less than assumed for the a2000 Table and the experience from the 2000-2004 experience study exhibited a similar relationship. For example, for attained ages 95-99, the 2000-2004 experience shows an $\mathrm{A} / \mathrm{E}$ of $128 \%$ for males ( 1,477 deaths) and $108 \%$ for females ( 3,505 deaths). The Team did not have any other explanation for why the experience data mortality rates would be so much greater than the a2000 Table mortality rates. The Team did review preliminary experience data from 2005 through 2008 and noted a similar relationship to the a2000 Table. Therefore, the Team decided to continue this relationship in the final table.

For the higher ages in the 2012 IAM Table, the Team graduated the underlying experience data using individual age data up to age 99. The results of the graduation, compared to the a2000 Table, ranges from $120 \%$ to $130 \%$ for males (consistent with data), and $99 \%$ to $133 \%$ for females (consistent with data overall, but a very steep slope within the age range).

Table 5 below compares the graduated rates at ages 90,95 and 99 to other predecessor mortality tables.

## Table 5 - Comparison of Mortality Rates (1000qx) At High Attained Ages

| Table | Age 90 |  | Age 95 |  | Age 99 |  |
| :--- | ---: | :---: | ---: | :---: | :---: | :---: |
|  | Male | Female | Male | Female | Male | Female |
| 2012 IAM Graduated Data | 135.89 | 107.00 | 216.65 | 171.92 | 304.13 | 296.03 |
| a2000 Table | 124.61 | 112.76 | 180.24 | 174.49 | 233.37 | 233.03 |
| 1994 GAM Basic projected to 2002 | 159.25 | 122.05 | 247.20 | 197.05 | 321.39 | 273.83 |
| 2008 VBT, NS | 139.33 | 104.24 | 227.67 | 159.48 | 306.99 | 240.15 |
| 2006 SSA | 177.64 | 138.94 | 277.94 | 226.89 | 354.02 | 299.72 |

Table 6 below examines more closely the female A/E experience for ages 95 to 99 . Upon further examination, it appeared that the female $\mathrm{A} / \mathrm{E}$ ratios might have been skewed upward at and near age 99 by large amount claims. The Team decided the amount-based experience at these highest ages lacked sufficient credibility and did not make further adjustment to the underlying experience.

Table 6-2000-04 Experience for Ages 95 to 99

|  |  | Male |  |  |  |  |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | A/E by <br> Amount | A/E by <br> Count | \# of <br> Deaths | A/E by <br> Amount | Female <br> A/E by <br> Count | \# of <br> Deaths |
| 95 | $110 \%$ | $138 \%$ | 511 | $95 \%$ | $118 \%$ | 1,036 |
| 96 | $156 \%$ | $142 \%$ | 385 | $95 \%$ | $125 \%$ | 886 |
| 97 | $144 \%$ | $143 \%$ | 268 | $107 \%$ | $135 \%$ | 733 |
| 98 | $121 \%$ | $156 \%$ | 203 | $128 \%$ | $124 \%$ | 487 |
| 99 | $99 \%$ | $130 \%$ | 112 | $152 \%$ | $125 \%$ | 363 |

The Team also desired to utilize a method that appropriately extrapolated the mortality for ages above age 99 and decided upon using Kannisto's formula. This formula is similar to the Gompertz formula (where the force of mortality increases by the same percentage amount at all ages), but Kannisto's formula is of the form $\mathrm{X} /(1+\mathrm{X})$, so that when mortality is low, the percentage increase in mortality by age is fairly constant, but as mortality becomes large, the increases get smaller. Kannisto's formula has been described as providing the best fit for data from ages 80-95 for a number of countries. ${ }^{5}$

Kannisto's formula was parameterized against the data for ages $80-95$ and the rates for ages $96+$ were used for the 2002 Experience Table. Table 7 below shows the results of the formula.

Table 7 - Results of Kannisto Extrapolation at Older Ages

|  | Male <br> Qx <br> Actual | Qx <br> Kannisto | Ratio: <br> Kannisto/ <br> Actual | Increase <br> Kannisto <br> Qx | Female <br> Qx <br> Actual | Qx <br> Kannisto | Ratio: <br> Kannisto/ <br> Actual | Increase <br> Kannisto <br> Qx | Ratio: <br> Female/ <br> Male |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 80 | 0.04471 | 0.04487 | $100.4 \%$ | $12.3 \%$ | 0.03134 | 0.03357 | $107.1 \%$ | $12.9 \%$ | $74.8 \%$ |
| 81 | 0.04932 | 0.05036 | $102.1 \%$ | $12.2 \%$ | 0.03514 | 0.03785 | $107.7 \%$ | $12.8 \%$ | $75.2 \%$ |
| 82 | 0.05708 | 0.05646 | $98.9 \%$ | $12.1 \%$ | 0.04844 | 0.04265 | $88.1 \%$ | $12.7 \%$ | $75.5 \%$ |
| 83 | 0.06524 | 0.06322 | $96.9 \%$ | $12.0 \%$ | 0.04645 | 0.04802 | $103.4 \%$ | $12.6 \%$ | $76.0 \%$ |
| 84 | 0.06517 | 0.07069 | $108.5 \%$ | $11.8 \%$ | 0.05071 | 0.05399 | $106.5 \%$ | $12.4 \%$ | $76.4 \%$ |
| 85 | 0.07673 | 0.07893 | $102.9 \%$ | $11.7 \%$ | 0.06059 | 0.06064 | $100.1 \%$ | $12.3 \%$ | $76.8 \%$ |
| 86 | 0.08303 | 0.08799 | $106.0 \%$ | $11.5 \%$ | 0.06577 | 0.06801 | $103.4 \%$ | $12.2 \%$ | $77.3 \%$ |

Table 8 below compares the resulting graduated rates to the mortality rates for other predecessor tables for select ages 90,95 and 99.

Table 8 - Comparison of Mortality Rates (1000qx) At High Attained Ages

|  | Age 90 |  | Age 95 |  | Age 99 |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Table | Male | Female | Male | Female | Male | Female |
| 2002 Experience Graduated Table | 135.89 | 107.00 | 216.65 | 171.92 | 304.13 | 296.03 |
| Kannisto Extrapolation | 133.20 | 105.84 | 210.96 | 174.79 | 286.78 | 246.73 |
| a2000 | 124.61 | 112.76 | 180.24 | 174.49 | 233.37 | 233.03 |
| 1994 GAM Basic projected to 2002 | 159.25 | 122.05 | 247.20 | 197.05 | 321.39 | 273.83 |
| 2008 VBT, NS | 139.33 | 104.24 | 227.67 | 159.48 | 306.99 | 240.15 |
| 2006 SSA | 177.64 | 138.94 | 277.94 | 226.89 | 354.02 | 299.72 |

The Team decided to use the graduated experience data rates up to age 95 and the Kannisto extrapolated rates for ages 96 and above.

Similar to the 2008 VBT Table, the Team decided to cap the mortality at the oldest ages, but decided upon a rate of 0.400 rather than the 0.450 used in the 2008 VBT. The decision to use 0.400 rather than 0.450 was based on information presented at the Society of Actuaries 2011 Living to 100 Symposium, which suggested there was some evidence that mortality did not end at 0.450 or 0.400 but that the process of aging could be slowed down, which would either increase a person's life span or reduce the impact of disease. Given that the difference in the ultimate mortality rate as these extreme ages has little bearing on the resulting reserve levels, the Team went with the lower level.

## V - The 2012 Individual Annuity Mortality Basic Table

The previous sections within this report describe the development of the 2002 experience table. The next step was to project this with improvement factors to 2012 to create the 2012 Individual Annuity Mortality Basic Table (2012 IAM Basic Table). The Team also developed a set of improvement or projection factors to improve mortality beyond 2012.

The improvement factors for 2013 and beyond were developed first. The Team looked at population improvement rates over a number of historical periods. Different sources were considered (Social Security Administration, U.S. Life Tables developed by the Centers for Disease Control and Prevention, and data published by the Human Mortality Database), all of which showed similar results. In addition, the Team compared the historical improvement rates to existing improvement assumptions including Scale AA, Scale G and the recently published improvement rates from the Canadian Institute of Actuaries. ${ }^{6}$ Historical improvement in annuity experience would have been preferred, but homogeneous data was not available. Tables 9 and 10 below show a comparison of the various improvement factors for male and female risks, respectively.

Table 9 - Comparison of Mortality Improvement for Various Sources - Male Risks

| $\begin{gathered} \text { Male } \\ \text { Age } \\ \hline \end{gathered}$ | $\begin{gathered} \text { Social Sect } \\ \text { Actual } \\ \mathbf{1 9 9 0 - 2 0 0 0} \\ \hline \end{gathered}$ | $\begin{aligned} & \hline \text { rity Improv } \\ & \text { Actual } \\ & \mathbf{2 0 0 0 - 2 0 0 6} \\ & \hline \end{aligned}$ | ment Rates <br> Actual <br> 1990-2006 | - 2010 Trus <br> Forecast <br> 2010-2030 | tees Report Average SSA 2002-2006 | Scale AA | Scale G | CIA <br> Proposal |

| 95 | $-0.9 \%$ | $0.7 \%$ | $-0.3 \%$ | $0.4 \%$ | $1.1 \%$ | $0.2 \%$ | $0.6 \%$ | $0.5 \%$ |  |

In looking more closely at the historical SSA improvement for the 2000 to 2006 years, the Team identified there was both improvement and dis-improvement from year-to-year. Years 2004 and 2006 showed high improvement for most ages whereas the year 2003 showed dis-improvement. In determining the average mortality improvement, the improvement was not floored at zero, allowing for the dis-improvement to be considered. In addition, the Team discussed whether some of the recent improvement in mortality in the actual SSA data could be explained by cohorts of smokers and ex-smokers being replaced by cohorts of non-smokers. This theory raised several questions such as:

1. Whether the higher level of improvement should be used to adjust the base table to 2012 ?
2. The point at which to assume a steady state is reached?
3. Whether these higher improvement trends were applicable to annuitants, given that they have a lower starting level of mortality than the population? Also, should the fact that smokers are under-represented in annuity populations be considered in our adjustments?

An additional consideration of the Team was that recent group annuity experience from 1993-2002 exhibited mortality improvement in line with scale AA. The Team believed that group annuity mortality would be lower than population but would not have the same level of anti-selection as individual annuity mortality.

The Team determined to use the SSA data as its primary source. The SSA had three separate forecasts which represented a low-cost set (Alternative I), an intermediate set (Alternative II) and a high-cost set (Alternative III). The SSA figures reflected in Tables 9 and 10 above are from their intermediate forecast (Alternative II).

The Team considered the actual SSA improvement rates for the period 1990-2006, as well as the average improvement rates assumed by the SSA in their 2010 Trustees report for years 2012-2022, and developed a set of improvement factors that are equal to or slightly ( $0.1 \%$ to $0.4 \%$ ) higher than the SSA 2012-2022 improvement factors for ages 50-95. (Note: Based upon clarification of approach from discussions with SSA actuaries and supported by various research and emerging experience, the Team determined the SSA improvement for ages $65+$ to be too conservative (i.e., low) for an annuity valuation table.) Therefore, an additional improvement level of $0.4 \%$ for ages 65 to 82 and $0.2 \%$ for ages $87+$ was added. The adjustment to the improvement was graded from $0.4 \%$ to $0.2 \%$ between ages 82 and 87 . This adjustment was the same for males and females. For younger ages, a simple $1 \%$ assumption was made. For older ages, the improvement rates grade to zero at age 105 . The Team has named the improvement Scale G2, as it replaces Scale G as the scale used for individual annuity valuation. Scale G2 is shown in Table 11, below. Table 12 compares the annualized improvement in Scale G2 to that of the U.S. Life Tables over various time periods.

Table 11 - Scale G2

|  | G2 Improvement |  |
| ---: | :---: | :---: |
| Age | Male | Female |
| $<50$ | $1.0 \%$ | $1.0 \%$ |
| 50 | $1.0 \%$ | $1.0 \%$ |
| 60 | $1.5 \%$ | $1.3 \%$ |
| 80 | $1.5 \%$ | $1.3 \%$ |
| 90 | $0.7 \%$ | $0.6 \%$ |
| 100 | $0.2 \%$ | $0.2 \%$ |
| 105 | $0.0 \%$ | $0.0 \%$ |

Table 12-Annualized Annual Improvement

| $2000-06$ | $1.7 \%$ | $2.7 \%$ | $1.9 \%$ | $1.1 \%$ | $1.6 \%$ | $1.9 \%$ | $1.4 \%$ | $0.8 \%$ |
| Scale G2 | $1.5 \%$ | $1.5 \%$ | $1.3 \%$ | $0.6 \%$ | $1.3 \%$ | $1.3 \%$ | $1.2 \%$ | $0.5 \%$ |

To create the 2012 IAM Basic Table, the Team projected the 2002 experience table for four years using actual SSA improvement from 2002 to 2006 (where 2002 is the mid-point of the underlying 2000-04 experience data, consistent with the experience study used to create the 2002 experience table). The Team looked at limited population data that indicated that population improvement rates from 2006 to 2009 were not inconsistent with Scale G2; therefore, the Team projected the rates from 2006-2012 (six years) using Scale G2. Tables 13 and 14 below show the actual SSA improvement rates for 1990 through 2006 and 2002 through 2006, and the SSA assumed improvement rates for 2012 through 2022, Scale G2, the 2002 experience table rates and the 2012 IAM Basic Table rates for male and female risks, respectively. Also, please see Exhibit I for the 2012 IAM Basic Table rates.

Table 15 below contains the analysis for the 2012 IAM Table and the impact of the projection scale 40 years out, to 2052. The 2012 table results in mortality rates, which, at key ages, are significantly lower than those in the a2000 Table, even without future improvement. For example, male rates are $33 \%$ lower at age 75 and $18 \%$ lower at age 85 .

Table 15 - Relationship of 2012 IAM Table with and without Projection to a2000 Table and Female to Male

|  | Projected Basic 1000qx as of: |  |  |  | Ratio to a2000 Table |  |  |  | Ratio: Female to Male |  |

## VI - The 2012 Individual Annuity Mortality Period Table

The 2012 IAM Period Table is the 2012 IAM Basic Table with the margins as determined by LATF, but without future projection. To develop the margins, the Team reviewed the approach taken for developing the margins used in the a2000 Table and discussed with LATF whether there was a need to vary the approach to determining the margin or the actual level of margin from that used in developing the a2000 Table, with a recommendation that the Team did not see a compelling reason to vary. LATF agreed no changes in the approach or level of margin were required. Thus, the resulting margin recommended by LATF is $10 \%$ for all ages up to and including 100. The margin then grades down $1 \%$ per year for ages 100 until the ultimate mortality cap of 0.40000 is invoked. This results in a margin of zero beginning at age 106 for males and 108 for females. The table omega is 120 where the mortality rate is set to 1.00000 . The Team determined there was no need to smoothly grade from 0.40000 to 1.00000 as there was little difference on the impact of reserves. See Exhibit II for the 2012 IAM Period Table.

## VII - The 2012 Individual Annuity Reserve Table and Projection Factors

To develop the 2012 Individual Annuity Reserve Table (2012 IAR Table), the Team concluded it made sense to create a generational mortality table through the use of projection factors. These projection factors are applied to the table each valuation year, rather than using a static table which can become dated more quickly. The Team used the same approach as for the improvement factors described in Section VI of this report. For future projection, the Team decided to use Scale G2, without further modification. An example of the development of a generational mortality table through application of projection factors is shown in Exhibit IV.

## VIII - Validation of 2012 IAM Table

In order to test the overall fit of the resulting table to the underlying 2000-2004 experience, the Team back-tested the table by recalculating the $\mathrm{A} / \mathrm{E}$ ratio where the expected basis was the 2012 IAM Table (i.e., without margin) adjusted to 2002, the mid-point of the underlying experience. The purpose of this test was to ensure that the resulting table, after the various adjustments, graduation and smoothing compared to the underlying experience as the Team intended. The Team observed the overall fit to be quite good at the core ages (i.e., 65 through 95 ) and somewhat less at other ages, where different data was used. The Team concluded this was appropriate and the results of the back-testing did not warrant additional modification to the table. Table 16 below shows the results of the back-testing.

## Table 16 - Comparison of 2012 IAM Basic Table (Adjusted to 2002) to 2000-2004 Experience

| Attained Age Group | Male A/E Ratio | Female A/E Ratio |
| :---: | :---: | :---: |
| $\mathbf{6 0 - 6 4}$ | $111 \%$ | $112 \%$ |
| $\mathbf{6 5 - 6 9}$ | $100 \%$ | $103 \%$ |
| $\mathbf{7 0 - 7 4}$ | $100 \%$ | $102 \%$ |
| $\mathbf{7 5 - 7 9}$ | $100 \%$ | $99 \%$ |
| $\mathbf{8 0 - 8 4}$ | $100 \%$ | $100 \%$ |
| $\mathbf{8 5 - 8 9}$ | $100 \%$ | $102 \%$ |
| $\mathbf{9 0 - 9 4}$ | $101 \%$ | $100 \%$ |
| $\mathbf{9 5 - 9 9}$ | $107 \%$ | $105 \%$ |

In addition, the Team tested the 2012 IAM Table to the preliminary 2005-2008 experience data. The Team determined there was no evidence to suggest withholding the introduction of the 2012 Table in order to obtain more data. Table 17 shows the results of the testing against the 2005-2008 preliminary experience data. The Expected basis is the 2012 IAM table (i.e., without margin) adjusted to January 1, 2007, the mid-point of the underlying experience.

Table 17 - Comparison of 2012 IAM Basic Table (Adjusted to January 1, 2007) to Preliminary 2005-2008 Experience

| Attained Age Group | Male A/E Ratio | Female A/E Ratio |
| :---: | :---: | :---: |
| $60-64$ | $110 \%$ | $129 \%$ |
| $65-69$ | $94 \%$ | $99 \%$ |
| $70-74$ | $105 \%$ | $99 \%$ |
| $75-79$ | $102 \%$ | $103 \%$ |
| $80-84$ | $104 \%$ | $98 \%$ |
| $85-89$ | $102 \%$ | $96 \%$ |
| $90-94$ | $107 \%$ | $105 \%$ |
| $95-99$ | $99 \%$ | $107 \%$ |

## IX - Impact to Reserves

The Team analyzed the impact of the 2012 Individual Annuity Reserve (2012 IAR) Table, which includes both the projection factors and margin, to the current a2000 Table, as well as to annuity reserves. Figures 3, 4, 5 and 6 below compare the mortality rates per 1,000 of the 2012 IAM Table, the 2012 IAR Table to the a2000 Table and a2000 Valuation Table.

Figure 3

Female Risks, Ages 65-90

Figure 8
Mortality Rate per 1,000 Comparison
Proposed 2012 Table to a2000 Table Female Risks, Ages 91-115

The Team also prepared sample reserve calculations using $5 \%$ interest and proposed mortality and compared them to reserves using a2000 table. In performing the review of the impact to reserves of the IAR Table, the Team compared initial reserves and reserves 10 years after issue for select ages as shown in Tables 18 and 19 below.

Table 18 - Comparison of Reserves at Issue

|  |  | Initial Reserves per $\$ 1,000$ <br> @ 5\% Interest |  |  | Percentage Increase |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | a2000 | $\begin{array}{\|c\|} \hline 2012 \text { w/o } \\ \text { Improvement } \\ \hline \end{array}$ | $\begin{array}{\|c\|} \hline 2012 \text { with } \\ \text { Improvement } \\ \hline \end{array}$ | 2012 w/o Improvement | Adding Improvement | $\begin{aligned} & \hline \text { Total } \\ & 2012 \\ & \hline \end{aligned}$ |
| Life Annuity at Age 65 | Male | 11.60 | 12.37 | 12.76 | 6.6\% | 3.1\% | 9.9\% |

## EXHIBIT IV

Generational Mortality Table Development

## EXHIBIT IV

## Example of Generational Mortality Table and Use of Projection Factors

In order to develop generational mortality table rates, the mortality rate for a person age x in year $(2012+\mathrm{n})$ determined as follows:

$$
q_{x}^{2012+n}=q_{x}^{2012} *\left(1-G 2_{x}\right)^{n}
$$

where,

- G2x is annual rate of mortality improvement for age x
- $\mathrm{q}_{\mathrm{x}}$ is the mortality rate from 2012 Individual Annuity Mortality Period Table

The following table illustrates the development of the 2012 IAR Mortality Table from the 2012 IAM Period Table

Illustration of Development of 2012 IAR Mortality Table, which is a Generation Mortality Table from the 2012 IAM Period Table

| Age | 2012 | 2013 | 2014 | 2015 | 2016 | 2017 | 2018 | $\ldots$ | 2070 |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 65 | $\mathrm{q}_{65}{ }^{2012}$ | $\mathrm{q}_{65}{ }^{2013}$ | $\mathrm{q}_{65}{ }^{2014}$ | $\mathrm{q}_{65}{ }^{2015}$ | $\mathrm{q}_{65}{ }^{2016}$ | $\mathrm{q}_{65}{ }^{2017}$ | $\mathrm{q}_{65}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{65}{ }^{2070}$ |
| 66 | $\mathrm{q}_{66}{ }^{2012}$ | $\mathrm{q}_{66}{ }^{2013}$ | $\mathrm{q}_{66}{ }^{2014}$ | $\mathrm{q}_{66}{ }^{2015}$ | $\mathrm{q}_{66}{ }^{2016}$ | $\mathrm{q}_{66}{ }^{2017}$ | $\mathrm{q}_{66}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{66}{ }^{2070}$ |
| 67 | $\mathrm{q}_{67}{ }^{2012}$ | $\mathrm{q}_{67}{ }^{2013}$ | $\mathrm{q}_{67}{ }^{2014}$ | $\mathrm{q}_{67}{ }^{2015}$ | $\mathrm{q}_{67}{ }^{2016}$ | $\mathrm{q}_{67}{ }^{2017}$ | $\mathrm{q}_{67}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{67}{ }^{2070}$ |
| 68 | $\mathrm{q}_{68}{ }^{2012}$ | $\mathrm{q}_{68}{ }^{2013}$ | $\mathrm{q}_{68}{ }^{2014}$ | $\mathrm{q}_{68}{ }^{2015}$ | $\mathrm{q}_{68}{ }^{2016}$ | $\mathrm{q}_{68}{ }^{2017}$ | $\mathrm{q}_{68}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{68}{ }^{2070}$ |
| 69 | $\mathrm{q}_{69}{ }^{2012}$ | $\mathrm{q}_{69}{ }^{2013}$ | $\mathrm{q}_{69}{ }^{2014}$ | $\mathrm{q}_{69}{ }^{2015}$ | $\mathrm{q}_{69}{ }^{2016}$ | $\mathrm{q}_{69}{ }^{2017}$ | $\mathrm{q}_{69}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{69}{ }^{2070}$ |
| $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ | $\ldots$ |
| 120 | $\mathrm{q}_{120}{ }^{2012}$ | $\mathrm{q}_{120}{ }^{2013}$ | $\mathrm{q}_{120}{ }^{2014}$ | $\mathrm{q}_{120}{ }^{2015}$ | $\mathrm{q}_{120}{ }^{2016}$ | $\mathrm{q}_{120}{ }^{2017}$ | $\mathrm{q}_{120}{ }^{2018}$ | $\ldots$ | $\mathrm{q}_{120}{ }^{2070}$ |
|  |  |  |  |  |  |  |  |  |  |

The following is an example of the mortality table rates for years 2013 through 2018. The table is based on the 2012 IAM Period Table for Male risks, using Scale G2, for issue years 2013

|  |  |  | Values of 1000qx |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age | $\mathbf{1 0 0 0} \mathbf{q}_{\mathbf{x}} \mathbf{2 0 1 2}$ | $\mathbf{G 2}_{\mathbf{x}}$ | $\mathbf{2 0 1 3}$ | $\mathbf{2 0 1 4}$ | $\mathbf{2 0 1 5}$ | $\mathbf{2 0 1 6}$ | $\mathbf{2 0 1 7}$ | $\mathbf{2 0 1 8}$ |
| $\mathbf{6 5}$ | 8.106 | 0.015 | 7.984 | 7.865 | 7.747 | 7.630 | 7.516 | 7.403 |
| $\mathbf{6 6}$ | 8.548 | 0.015 | 8.420 | 8.293 | 8.169 | 8.047 | 7.926 | 7.807 |
| $\mathbf{6 7}$ | 9.076 | 0.015 | 8.940 | 8.806 | 8.674 | 8.544 | 8.415 | 8.289 |
| $\mathbf{6 8}$ | 9.708 | 0.015 | 9.562 | 9.419 | 9.278 | 9.138 | 9.001 | 8.866 |
| $\mathbf{6 9}$ | 10.463 | 0.015 | 10.306 | 10.151 | 9.999 | 9.849 | 9.701 | 9.556 |

${ }^{2}$ P-Spline formula denoted as $q(i) x, t=\exp \{\log (q(i) x, t)+Z x \hat{S} x, t\}$ whereby $q(i) x, t$ is the force of mortality for each age $x$ and for each year $t$. Ŝx,t is the standard deviation of the $\log$ mean value of $q(i) x, t$. $Z$ is a standard normal variable for use in generating scenarios. Further details on the P-Spline methodology and the Mortality Projection Spreadsheet v3.0 can be found in the Continuous Mortality Investigation Working Paper 15 (2005), pp. 12-15 and Revised Working Paper 20 produced by The Faculty of Actuaries and Institute of Actuaries.
